

Classic Nintendo Games are (NP-)Hard

February 25, 2013

Abstract

We prove NP-hardness results for five of Nintendo’s largest video game franchises: Mario, Donkey Kong, Legend of Zelda, Metroid, and Pokémon. Our results apply to Super Mario Bros. 1, 3, Lost Levels, and Super Mario World; Donkey Kong Country 1–3; all Legend of Zelda games except Zelda II: The Adventure of Link; all Metroid games; and all Pokémon role-playing games. For Mario and Donkey Kong, we show NP-completeness. In addition, we observe that several games in the Zelda series are PSPACE-complete.

1 Introduction

A series of recent papers have analyzed the computational complexity of playing many different video games [1, 4, 5], yet the most well-known Nintendo games of our youth have yet to be included among these results. In this paper, we consider some of the best-known Nintendo games of all time—Mario, Donkey Kong, Legend of Zelda, Metroid, and Pokémon—and prove that it is NP-hard to play generalized versions of many games in these series. In particular, our results for Mario apply to the NES games Super Mario Bros., Super Mario Bros.: The Lost Levels, Super Mario Bros. 3, and Super Mario World (developed by Nintendo); our results for Donkey Kong apply to the SNES games Donkey Kong Country 1–3 (developed by Rare Ltd.); our results for Legend of Zelda apply to all Legend of Zelda games (developed by Nintendo) except the side-scrolling Zelda II: The Adventure of Link; our results for Metroid apply to all Metroid games (developed by Nintendo); and our results for Pokémon apply to all Pokémon role-playing games (developed by Game Freak and Creatures Inc.).¹

Our results are motivated in particular by tool-assisted speed runs for video games. A *speed run* of a game is a play through that aims to achieve a fast completion time, usually performed by a human. In a *tool-assisted* speed run, the player uses special tools, such as emulators, to allow them to slow the game down to a frame-by-frame rate in order to achieve superhuman reflexes and timing. In some sense, tool assistance is not cheating because the rules of the game are still obeyed. The resulting speed runs are impressive to watch, as the paths taken by a tool-assisted player are

¹All products, company names, brand names, trademarks, and sprites are properties of their respective owners. Sprites are used here under Fair Use for the educational purpose of illustrating mathematical theorems.

usually traversed more-or-less optimally, and so the speed of the run comes down to the optimality of the path chosen rather than how it is traversed. A natural question arises: for a given game, what is the fastest possible speed run?

For these games, we consider the decision problem of reachability: given a stage or dungeon, is it possible to reach the goal point t from the start point s ? If it is hard to decide even this question, then it is certainly hard to find an optimal path. Our results apply to generalizations of the games where we *only* generalize the map size and leave all other mechanics of the games as they are in their original settings. All of our NP-hardness proofs are by reduction from 3-SAT, and the proofs for Mario, Donkey Kong, Legend of Zelda, and Metroid rely on a common construction, while the proof for Pokémon is based on a reduction to Push-1 [2]. We show that certain Zelda games are in fact PSPACE-complete, by reducing from PushPush-1 [3].

We can obtain some positive results if we bound the “memory” of the game. For example, recall that in Super Mario Bros. everything substantially off screen resets to its initial state. Thus, if we generalize the stage size in Super Mario Bros. but keep the screen size constant, then reachability of the goal can be decided in polynomial time: the state space is polynomial in size, so we can simply traverse the entire state space and check whether the goal is reachable. Similar results hold for the other games if we bound the screen size in Donkey Kong Country or the room size in Legend of Zelda, Metroid, and Pokémon. The screen-size bound is more realistic (though fairly large in practice), while there is no standard size for rooms in the latter three games.

Organization. In Section 2, we present a general schematic used in our reductions for Mario, Donkey Kong, Legend of Zelda, and Metroid. We show that, if the basic gadgets in the construction are implemented correctly, then the reduction from 3-SAT follows. In Section 3, we prove that generalized Super Mario Bros. is NP-hard by constructing the appropriate gadgets for the construction given in Section 2. In Sections 4, 5, and 6, we do the same for generalized Donkey Kong Country, Legend of Zelda, and Metroid, respectively. In Section 7, we prove that generalized Pokémon is NP-hard by giving a reduction from 3-SAT using the construction given in [2], by constructing the six basic gadgets it requires.

2 Framework for Platform Games

The general decision problem we consider for platform games is to determine whether it is possible to get from a given start point to a given goal point. This is a natural problem because the main challenge of platform games is to maneuver around enemies and obstacles in order to reach the end of each stage.

We use a general framework for proving the NP-hardness of platform games, illustrated in Figure 1. This framework is similar to the NP-hardness proof of PushPush-1 [2]. With this framework in hand, we can prove hardness of individual games by just constructing the necessary gadgets.

The framework reduces from the classic NP-complete problem 3-SAT: decide whether a 3-CNF Boolean formula can be made “true” by setting the variables appropriately. The player’s character starts at the position labeled Start, then proceeds to the Variable gadgets. Each Variable gadget forces the player to make an exclusive choice of “true” (x) or “false” ($\neg x$) value for a variable in the formula. Either choice enables the player to follow paths leading to Clause gadgets, corresponding to the clauses containing that literal (x or $\neg x$). These paths may cross each other, but Crossover

Figure 1: General framework for platform games

gadgets prevent the player from switching between crossing paths. By visiting a Clause gadget, the player can “unlock” the clause (a permanent state change), but cannot reach any of the other paths connecting to the Clause gadget. Finally, after traversing through all the Variable gadgets, the player must traverse a long “check” path, which passes through each Clause gadget, to reach the Finish position. The player can get through the check path if and only if each clause has been unlocked by some literal. Therefore, it suffices to implement Start, Variable, Clause, Finish, and Crossover gadgets to prove NP-hardness of each platform game.

The specific properties our gadgets must satisfy are the following.

Start and Finish. The Start and Finish gadgets contain the starting point and goal for the character, respectively. In most of our reductions, these gadgets are trivial, but in some cases we need the player to be in a certain state throughout the construction, which we can force by making the Finish accessible only if the player is in the desired state, and the desired state may be entered at the Start. Specifically, in the case of Mario, we need Mario to be big throughout the stage, so we put a Super Mushroom at the start and a brick at the Finish, which can be broken through only if Mario is big.

Variable. Each Variable gadget must force the player to choose one of two paths, corresponding to the variable x_i or its negation $\neg x_i$ being chosen as the satisfied literal, such that once a path is taken, the other path can never be traversed. Each Variable gadget must be accessible from and only from the previous Variable gadget, independent of the choice made in the previous gadget, in such a way that entering from one literal does not allow traversal back into the negation of the literal.

Clause and Check. Each Clause gadget must be accessible from and only from the literal paths corresponding to the literals appearing in the clause in the original Boolean formula. In addition, when the player visits a Clause gadget, they may perform some action which “unlocks” the Clause.

The Check must pass through every Clause such that the player may pass through the Clause via the Check if and only if the Clause is unlocked. The Check is accessible only if all the Variable gadgets have been visited from Clauses. If the player traverses the entire Check, they may access the Finish.

Crossover. The Crossover must allow traversal via two passages that cross each other, such that there is no leakage between the two unless both passages have already been traversed.

Remark 2.1. The crossover gadgets only needs to be *unidirectional*, in the sense that each of the two crossing paths only needs to be traversed in one direction. This is sufficient because, for each path visiting a clause from a literal, instead of backtracking to the literal after visiting the clause, we can reroute directly to visit the next clause, so the player is never required to traverse a clause–literal path in both directions.

3 Super Mario Bros.

Super Mario Bros. is a platform video game created by Shigeru Miyamoto, developed by Nintendo, published for the Nintendo Entertainment System (NES) in 1985. In the game, the player controls Mario, an Italian plumber, and must navigate through worlds full of enemies and obstacles to rescue the kidnapped Princess Toadstool from Bowser. The game spawned over a dozen sequels (SMB 2, SMB 3, Super Mario World, Super Mario 64, Super Mario Sunshine, Super Mario Galaxy, etc.) across various gaming platforms. Mario’s character became so popular that he became Nintendo’s mascot and appeared in over 200 games.

The gameplay in Super Mario Bros. is simple. Mario’s actions are limited to walking, running, crouching, and jumping. By combining these, Mario can perform more advanced actions. For example, if Mario crouches while running, he will crouch-slide, which will allow him to fit into narrow corridors while as Super Mario. Mario primarily defeats enemies by jumping on them, and he obtains items by hitting item blocks with his head by jumping from below. By default, Mario is small (one tile tall) and dies upon harmful contact with an enemy. Jumping on an enemy is usually non-harmful, though there are exceptions not encountered in our proof. If Mario obtains a Super Mushroom, then he becomes Super Mario, who is two tiles tall. Upon harmful contact, Super Mario reverts back to normal Mario. A key enemy in the game is the Koopa. Koopas come in two varieties. Green Koopas walk off cliffs, whereas Red Koopas turn around when they encounter a cliff. We use only Red Koopas in our construction. When Mario jumps on a Koopa, it hides in its shell, which Mario can then kick. Once kicked, a Koopa Shell slides with constant velocity and bounces off surfaces, activating blocks if it bounces off them. There are three types of blocks: normal blocks, which are inert; item blocks, which release an item upon activation; and bricks, which are destroyed upon activation. There are many other items and enemies in the game, but they do not play a role in our proofs so we do not include them here. For more information on the game, see [6].

In this section, we prove the following:

Theorem 3.1. *It is NP-complete to decide whether the goal is reachable from the start of a stage in generalized Super Mario Bros.*

First we prove NP-hardness. We use the general framework provided in Section 2, so it remains only to implement the gadgets. The Start and Finish gadgets are straightforward. The Start

gadget includes an item block containing a Super Mushroom which makes Mario into Super Mario (see Figure 2). The Super Mushroom serves two purposes: first, Super Mario is 2 tiles tall, which prevents him from fitting into narrow horizontal corridors, a property essential to our other gadgets; second, Super Mario is able to destroy bricks whereas normal Mario cannot. In order to force the player to take the Super Mushroom in the beginning, we block off the Finish gadget with bricks (see Figure 3).

Figure 2: Left: Start gadget for Mario. Right: The item block contains a Super Mushroom

Figure 3: Finish gadget for Mario

Next, we implement the Variable gadget, illustrated in Figure 4. There are two entrances, one from each literal of the previous variable (if the variable is x_i , the two entrances come from x_{i-1} and $\neg x_{i-1}$). Once Mario falls down, he cannot jump back onto the ledges at the top, so Mario cannot go back to a previous variable. In particular, Mario cannot go back to the negation of the literal he chose. To choose which value to assign to the variable, Mario may fall down either the left passage or the right.

Now we present the Clause gadget, illustrated in Figure 5. The three entrances at the top come from the three literals that appear in the clause. To unlock the clause, Mario jumps onto a Red Koopa, kicks its shell down, which bounces and breaks all the bricks in the corridor at the bottom, opening the path for later checking. Note that falling down is no use because Super Mario cannot fit into the narrow corridor unless he gets hurt by the Koopa, in which case he will not be able to reach the goal. There is not enough space for Mario to run and crouch-slide into the corridor. The gap at the bottom of the wide corridor is so the Koopa Shell does not unlock other clauses.

Finally, we implement the Crossover gadget, illustrated in Figure 6. There are four entrances/exits: top left, top right, bottom left, and bottom right. The Crossover gadget is designed so that, if Mario

Figure 4: Variable gadget for Mario

Figure 5: Clause gadget for Mario

enters from the top left, then he can only exit through the bottom right, and vice versa, and similarly for the top right and bottom left. Suppose Mario enters from the top left. He cannot jump onto the ledge on the top right because of the vertical set of blocks in the middle. He cannot exit through the bottom left because the path is blocked. He can exit through the bottom right by jumping on the Red Koopa and kicking its shell down to the right, breaking the brick block, then dropping down and crouch-sliding through the opened gap. By symmetry, the same holds for the top right and bottom left. Note that this is unidirectional crossover, which suffices by Remark 2.1.

Figure 6: Crossover gadget for Mario

NP. To show that Super Mario Bros. is in NP, it suffices to show that, if there is a solution, then there is a solution whose size is at most polynomial in the input size. Suppose there is a solution and consider any path that Mario takes through the stage. This path needs to visit every enemy at most once. The only other permanent objects in the game are potential Koopa shells, but these can only slide and fall, so they must either fall down a bottomless pit eventually and leave the game, or they enter a cycle where they bounce back and forth between two walls. In either case, the shell can be ignored, because a perfect player gains nothing by jumping on the shell to stop it. Therefore there exists a solution that is polynomial in the size of the input.

Other Mario games. The NP-hardness from Theorem 3.1 holds just as well for the NES sequel, SMB: The Lost Levels (which is actually SMB2 in Japan) because the gameplay mechanics are exactly the same.

The construction does not quite work for the later games, because Mario can pick up Koopa shells. This issue does not affect the Clause gadget, but it breaks the Crossover gadget. Instead, we can tweak the Crossover gadget to work without using any Koopas, as shown in Figure 7. This unidirectional Crossover enables Mario to traverse left-to-right or bottom-to-top as follows. Approaching from the left, Mario may get hurt by the Goomba and revert back to his small state, then walk through the narrow corridor and pick up a Super Mushroom from the item block on the other side, allowing him to break through the brick. There is clearly no leakage to the bottom, nor leakage to the top since small Mario cannot break bricks. Furthermore, there is not enough

Figure 7: Modified Crossover gadget which works for later Mario games

space for Mario to run and crouch-slide through the gap. Approaching from the bottom, Mario may break the right brick on the lower level, jump onto the left brick of the lower level, break the left brick on the upper level, and jump onto the right brick of the upper level to proceed upwards. Because Mario must be big this entire time, he cannot fit through the narrow gaps on the sides and so there is no horizontal leakage. Also, Mario cannot enter this Crossover initially from the top or right.

Using this Crossover gadget, the construction extends to Super Mario Bros. 3 as well as Super Mario World. NP-completeness holds for SMB: The Lost Levels because the mechanics are identical to those of SMB. However, it is not clear that the problem remains in NP for SMB3 or beyond, because of Mario’s newfound ability to pick up Koopa shells.

4 Donkey Kong Country

Donkey Kong Country is a platform video game developed by Rare and published for the Super Nintendo Entertainment System (SNES) in 1994. Like Mario, the character of Donkey Kong was originally created by Shigeru Miyamoto, and appears in many other games as well. The premise of Donkey Kong Country is isomorphic to that of Super Mario Bros. In particular, King K. Rool has stolen Donkey Kong’s banana hoard, and the player controls Donkey Kong (and occasionally his small nephew Diddy Kong) to navigate through levels filled with enemies and obstacles in order to defeat K. Rool.

The gameplay of Donkey Kong Country is also quite simple. We only discuss gameplay mechanics necessary for our proof. For more information on the game, see [7]. Donkey Kong’s basic actions are walking, running, rolling, crouching, and jumping. He may also pick up Barrels and throw them, after which they roll along the ground until they hit a wall or an enemy, killing it. Donkey Kong can jump into Barrel Cannons, from which he may be fired in a straight line, defying gravity. Manual Barrel Cannons cycle through a preset set of angles at which Donkey Kong may be fired, which the player may choose with proper timing. Automatic Barrel Cannons fire Donkey Kong as soon as he jumps in. Zingers are enemies that resemble giant bees. They kill Donkey Kong on contact, and cannot be killed except by Barrels.

In this section, we prove the following:

Theorem 4.1. *It is NP-complete to decide whether the goal is reachable from the start of a stage in generalized Donkey Kong Country.*

We show that Donkey Kong Country is NP-hard by reducing from 3-SAT. As in the proof for Super Mario Bros., we use the general framework provided in Section 2. The Start and Finish gadgets are trivial; they are simply the beginning and end parts of the level, respectively. The Variable gadget is simply analogous to the variable gadget for Mario, replacing blocks with the appropriate terrain from Donkey Kong Country. The clause gadget, illustrated in Figure 8, is similar to that in Mario. When visiting the clause from a variable, Donkey Kong must pick up the Barrel and toss it down, after which it rolls and kills the Zinger (bee). The Barrel Cannon above each platform is used to return upward, and the platforms are sufficiently high that, if Donkey Kong drops down, he cannot jump back up onto the platforms.

Figure 8: Clause gadget for Donkey Kong

The final check, illustrated in Figure 9, is straightforward. The illustration is not drawn to scale, but the idea is that at the end, Donkey Kong enters the Automatic Barrel Cannon on the right, which blasts him towards the Automatic Barrel Cannon on the left, which blasts him downward toward the goal. There are Zingers positioned in the path, one per clause (these are the same Zingers that are in the clause gadgets) so that Donkey Kong can reach the goal if and only if every Zinger is killed.

Finally, we must implement the crossover gadget (Figure 10), which is remarkably easy in Donkey Kong Country. Essentially, at every entrance/exit, there is a forward Automatic Barrel Cannon and a backward one. Therefore, the horizontal passage can be traversed without leakage to the vertical passage, and vice versa.

NP. Similar to Super Mario Bros., Donkey Kong Country is in NP because any solution path through the stage only needs to visit every enemy at most once. All other objects that affect the environment (various types of Barrels) make monotone progress toward eventual destruction upon collision with a wall or falling down a pit. Therefore, the length of the solution path is polynomially bounded in the input size.

Figure 9: Clause check for Donkey Kong

Figure 10: Crossover gadget for Donkey Kong

Other Donkey Kong games. Theorem 4.1 holds just as well for the sequels—Donkey Kong Country 2 and 3—because Zingers, Barrels, and Barrel Cannons are all present in these games.

5 The Legend of Zelda

The Legend of Zelda is a high fantasy flip-screen overhead adventure video game developed by Nintendo and published for the NES in 1986. Like the Super Mario and Donkey Kong series, the Zelda series has spawned over a dozen sequels across various gaming platforms. The series features a young male swordsman named Link, usually clad in a green tunic. In the original Legend of Zelda game, the player controls Link and ventures on a quest through dungeons, collecting items and defeating enemies and bosses to rescue the kidnapped Princess Zelda from the antagonist, Ganon. The premise of the SNES sequel, The Legend of Zelda: A Link to the Past, is roughly the same. Here we consider both versions, although we do not describe in much detail the items or enemies found in the games. Instead, we refer the interested reader to [8] and [9]. Unlike the previous games we studied, The Legend of Zelda is nonlinear and the player must acquire new items from dungeons in order to access previously inaccessible areas. The game world is set in an overworld, Hyrule, with self-contained dungeons scattered across the world.

We have two different types of proofs, using two different elements found in Zelda games. Pushable blocks play a large role in many puzzles in Zelda games, and we use these elements to prove that the original Legend of Zelda is NP-hard and that several later games are PSPACE-complete. The hookshot is also a recurring item in Zelda games (although it is absent from the original). With the hookshot, Link can grapple onto and pull himself towards distant objects. We use this item to prove that the rest of the Zelda games are NP-hard.

Block pushing. Generalized Legend of Zelda is NP-hard by reduction from a puzzle similar to Push-1, because Legend of Zelda contains blocks which may be pushed according to the same rules as in Push-1 [2], except that in Zelda, each block may be pushed at most once. Fortunately, all of the gadgets in the reduction for Push-1 found in [2] still function as intended when each block can be pushed at most once, with the possible exception of the Lock gadget. However, a simple modification to the Lock gadget (illustrated in Figure 11) suffices. (Here we assume that Link has no items, in particular, no raft.) Therefore we obtain

Theorem 5.1. *It is NP-hard to decide whether a given target location is reachable from a given start location in generalized Legend of Zelda.*

Several of the later Zelda games contain ice block puzzles. Ice blocks are pushed like normal blocks, except when pushed they slide all the way until they encounter an obstacle. These are the same rules as in PushPush1, which is PSPACE-complete, hence we get the following theorem.

Theorem 5.2. *It is PSPACE-complete to decide whether a given target location is reachable from a given start location in the generalized versions of the following games: Ocarina of Time, Majora’s Mask, Oracle of Seasons, The Minish Cap, and Twilight Princess.*

Hookshot. Unfortunately, the block-pushing reduction does not extend to many of the Legend of Zelda games because the rules of Push-1 do not allow the player to pull blocks, which is possible in those games. We now give a proof of NP-hardness for the SNES sequel, The Legend of Zelda: A

Figure 11: Modified Lock gadget for block pushing in Legend of Zelda

Link to the Past, taking advantage of the hookshot item, which allows Link to grapple onto certain distant objects and pull himself towards them.

Theorem 5.3. *It is NP-hard to decide whether a given target location is reachable from a given start location in generalized Legend of Zelda: A Link to the Past.*

The only elements of the game we use are the following. We use *treasure chests* and blocks which will serve as grapple targets. Link starts out with the hookshot (which can grapple onto treasure chests and pull Link towards them).

Although this game is not technically a platform game, we use the same framework provided in Section 2 here to reduce from 3-SAT. We do not need any special Start or Finish gadgets. The Variable gadget, illustrated in Figure 12, works as follows. Link approaches from either the top left or top right, depending on which value of the previous variable was chosen. Then Link hookshots onto the chest in the top center, then hookshots onto the chest in the center, and finally must make a choice at the bottom.

The Clause gadget is illustrated in Figure 13. The three corridors at the top correspond to the literals which appear in the clause. When Link visits one of these corridors, he may push the block forward, which allows him to hookshot onto the block from the right later on while traversing the Clause check (see Figure 14).

Finally, we implement the Crossover gadget, illustrated in Figure 15. To get across the gap, Link must hookshot across to the treasure chest on the opposite side. Link cannot turn, so there is no leakage between horizontal traversal and vertical traversal.

Theorem 5.3 extends easily to all later games (Link's Awakening, Ocarina of Time, Majora's Mask, Twilight Princess, etc.) because the hookshot and blocks are present. In the case of the 3D games, we attach a hookshot target onto the block (as blocks themselves are no longer valid hookshot targets), and add walls to the sides of platforms, since in 3D games Link can hookshot towards any visible direction.

Figure 12: Variable gadget for Zelda

Figure 13: Clause gadget for Zelda

Figure 15: Crossover gadget for Zelda

6 Metroid

Metroid is an action-adventure video game co-developed by Nintendo Research and Development 1 and Intelligent Systems, and published for the NES in 1986. Like the previous games we have described, Metroid continued to spawn numerous sequels across gaming platforms. The original Metroid, as well as Super Metroid (SNES), were two-dimensional side-scrolling flip-screen games. In Metroid, the player controls Samus, a female space bounty hunter, and explores planet Zebes to retrieve Metroids (life-draining creatures) which were stolen by Space Pirates. Like The Legend of Zelda, Metroid is an open-ended nonlinear game in which players must discover and acquire items in order to access previously inaccessible areas. However, unlike the world of Zelda, the world of Metroid is essentially one very large overworld with no nicely self-contained dungeons, and hence is at first glance much less structured.

The mechanics of Metroid are also simple. Samus can walk, jump, or shoot. Samus may shoot left, right, or upwards (but not downwards). In addition, when standing on the ground, Samus can enter Morph Ball mode, which makes her one tile tall instead of two, and allows her to roll. However, while in Morph Ball, Samus cannot attack or jump, but only roll left or right and fall. The only enemy in the game we use in our proof is the Zoomer, which is simply a creature that walks along whatever surface it adheres to, and deals damage to Samus upon contact, but may be killed by Samus' normal weapon. In addition, the game contains breakable blocks, which can be destroyed by Samus' weapon but regenerate after a short amount of time. For more details on the game, we refer the interested reader to [10].

In this section, we prove the following:

Theorem 6.1. *It is NP-complete to decide whether a given target location is reachable from a given start location in generalized Metroid.*

We use the same framework given by Section 2. In our construction, Samus has acquired no special items yet except the Morph Ball, and has 1 Energy point left, so she must not get hurt at all. The Start and Finish gadgets are trivial, and the Variable gadget is the same as in our proofs for Mario and Donkey Kong.

The first nontrivial gadget we implement is the Clause gadget (Figure 16). As opposed to the previous Clause gadgets we have constructed, the one for Metroid has the literals approaching the clause from below, with the clause checking on top. It works as follows. Samus approaches from

below, and can shoot upward through the gap and kill all the Zoomers (which are moving clockwise around the platform), freeing up the space for later traversal in Morph Ball mode. After killing the Zoomers, Samus cannot jump and sneak into the passageway, because it requires Morph Ball mode, and furthermore if this clause is not visited, then Samus cannot pass through from above because the corridor is completely filled with Zoomers.

Figure 16: Clause gadget for Metroid

The second nontrivial gadget is the Crossover gadget (Figure 17). The horizontal passage can clearly be traversed without leakage into the vertical passage. Moreover, the vertical passage can be traversed *upward* without leakage into the horizontal passage, as the blocks in the center are breakable, and Samus cannot jump and fit into the horizontal passage as it requires Morph Ball mode. This crossover gadget is unidirectional (in the vertical direction) which, by Remark 2.1, suffices.

Figure 17: Crossover gadget for Metroid

NP. Metroid is in NP because any solution path only needs to visit each enemy at most once and hence is polynomially bounded in length.

Other Metroid games. Theorem 6.1 holds just as well for all other Metroid games because the Morph Ball, Zoomers, and breakable rocks are all present in the sequel games. For the 3D Metroid games, one can modify this construction to have very small depth, so that the third dimension becomes irrelevant.

7 Pokémon

Pokémon is a series of overhead role-playing games developed by Game Freak for various handheld Nintendo consoles, including Game Boy, Game Boy Color, Game Boy Advance, and the Nintendo DS. There are various versions of Pokémon, but the core mechanics of the game are invariant throughout. The player controls a young teenager and wanders through the land capturing and training creatures called Pokémon (short for Pocket Monsters). At any one time, the player may hold up to six Pokémon in their team. Each Pokémon has a Level, which indicates roughly how experienced it is, as well as battle stats: attack, defense, speed, special attack, and special defense. In addition, each Pokémon has hit points (HP), which indicate how much damage it can take before “fainting”, as well as power points (PP) for each move, which indicates how many times it may use that move. Pokémon battles are two-player simultaneous move games, and in each round the Pokémon with higher speed attacks first. The battle ends when all of one trainer’s Pokémon have fainted.

Pokémon is NP-hard because it has blocks that the player can push according to the rules of Push-1 [2]. Therefore we immediately have

Theorem 7.1. *It is NP-hard to decide whether a given target location is reachable from a given start location in generalized Pokémon.*

In this section, we give an alternate proof that Pokémon is NP-hard using no elements of the game except enemy Trainers and the game’s battle mechanics (and thus no blocks). Therefore we obtain the following stronger result:

Theorem 7.2. *It is NP-complete to decide whether a given target location is reachable from a given start location in generalized Pokémon in which the only overworld game elements are enemy Trainers.*

We briefly describe the mechanism for enemy Trainer encounters in the Pokémon games. Each enemy Trainer has an orientation (which direction they are facing), a range of sight, and a set of Pokémon. If the player walks into the line of sight of the Trainer, the player is forced to stop, the Trainer walks toward the player until they are adjacent, and then battle ensues. Additionally, if the player approaches a Trainer from outside the Trainer’s line of sight (i.e., from behind or the sides), the player may talk to the Trainer, activating the battle. If the player wins the battle, the Trainer will not move or attack again.

We prove NP-hardness by reducing from 3-SAT. We use the same framework used to prove NP-hardness of Push-1 in [2]. Therefore, it suffices to implement the following gadgets: one-way, fork, H, no-reverse, lock, and XOR-crossover (as described below).

In our implementations, we use three kinds of objects. Walls, represented by dark grey blocks, cannot be occupied or walked through. Trainers’ lines of sight are indicated by translucent rectangles. We have two types of Trainers. Weak Trainers, represented by red rectangles, are Trainers that the player can defeat with certainty without expending any effort, i.e., without expending PP or taking damage. Strong Trainers, represented by blue rectangles, are Trainers that the player will always lose against.

We can implement weak and strong Trainers as follows. The player has no items, and only one Pokémon in his team, a Level 1 Gastly (or any Ghost-type Pokémon). The weak Trainer has a Level 100 Electrode, which certainly has a higher Speed than the Level 1 Gastly. The Electrode’s only

move is Self Destruct. Thus, when the player battles a weak Trainer, the Trainer's Electrode moves first and uses Self Destruct, which does no damage to Gastly because Self Destruct is a Normal-type attack and Gastly is Ghost-type. Therefore, the player defeats the weak Trainer without expending any PP or taking any damage. To implement a strong Trainer, we give the strong Trainer a Level 100 Alakazam with Psychic. Alakazam will clearly go first against Gastly and defeat Gastly with certainty by using Psychic.

We now implement each gadget. The one-way gadget, illustrated in Figure 18, is straightforward (no pun intended). We must show that, upon first encounter, the player may only traverse the one-way gadget from a to b . The player cannot enter through b because a Trainer is blocking the path. However, the Trainer can enter through a by walking into the Trainer's line of sight, which forces the Trainer to walk forward one tile, defeating the Trainer, and then walking around and through b .

Figure 18: One-way gadget for Pokémon

The fork gadget, illustrated in Figure 19, must force the player to choose either an a -to- b traversal or an a -to- c traversal. We show that this is the case. The player enters through a . If the player wants to exit through b , they walk into the Trainer's line of sight, luring the Trainer down and opening up the passage to b , but closing the passage to c . On the other hand, if the player wants to exit through c , they walk up to the Trainer and talk to him, disabling the Trainer, so that they may walk around and exit through c .

Figure 19: Fork gadget for Pokémon

The H gadget, illustrated in Figure 20, is supposed to satisfy the following requirements:

- Entrance must be from x or y ;
- Entrance from x must be followed by exit through x' , and similarly entrance from y must be followed by exit through y' ;
- x -to- x' traversal makes y -to- y' traversal impossible, and vice versa.

We now show that each of these requirements are met. Our gadget is symmetrical, so it suffices to prove that the x half of each requirement is met. The player cannot enter from x' , because he must walk into the Trainer's line of sight, luring the Trainer down and blocking the path completely. Furthermore, if the player enters from x , they must walk into the line of sight of the Trainer in

front of y' , who gets lured into the spot where the lines of sight overlap, blocking the path to y' from x . Therefore the player must exit through x' , which is easily done. Moreover, after doing this, the player cannot later traverse through the y -to- y' passage because the strong Trainer's line of sight is unblocked.

Figure 20: H gadget for Pokémon

The no-reverse gadget serves a similar function as the one-way gadget, except after traversing from a to b , the player cannot traverse it from b to a . This is implemented by the gadget in Figure 21. Clearly, the player cannot enter via b , because that lures the weak Trainer to block the passage. Suppose the player enters through a . They can safely walk to b , because the weak Trainer is blocking the bottom strong Trainer's line of sight. However, to reach b , the player must lure the weak Trainer out of the line of sight of the strong Trainer, hence the player may never return in the reverse direction.

Figure 21: No-reverse gadget for Pokémon

The lock gadget, illustrated in Figure 22, is supposed to satisfy the following requirements:

- Upon first encounter, it cannot be traversed from any of $\{a, b, v\}$; only passage from u to v is possible;
- After entrance from u , only v can be reached. This remains true even if re-entered from u later;
- After entrance from u , the state of the gadget may be unlocked to permit later passage from a to b ;

- After such later a -to- b traversal, all of $\{a, b, u\}$ are open to each other through the gadget.

We now show that our lock gadget satisfies these properties. Upon first encounter, the player may only enter from u , and furthermore only v may be reached from u . However, on the way to v , the player may stray left and lure out the Trainer blocking a -to- b traversal. This is the unlocking action. Finally, when traversing from a to b , the player may take a small detour north to lure out the Trainer blocking passage to u .

Figure 22: Lock gadget for Pokémon

Finally, we implement the XOR-crossover gadget, illustrated in Figure 23. We must show that the player may traverse from x to x' without leakage to y or y' , and traverse from y to y' without leakage to x to x' . By symmetry, it suffices to prove the former. Suppose the player enters from x . The second Trainer the player encounters gets lured north, unblocking the line of sight of the strong Trainer near y' , hence blocking the path to y' , and it is clear that the player cannot exit through y .

Figure 23: XOR-Crossover gadget for Pokémon

To show that Pokémon with only enemy Trainers is in NP, note that once a Trainer has been battled, they become inert. Moreover, each actual battle is bounded in length by a constant, because eventually all Pokémon must expend all their PP for their moves and use Struggle, which damages themselves. Therefore, the player may nondeterministically guess a solution path through the overworld, and for each battle nondeterministically guess the sequence of attacks to use.

Other Pokémon games. Theorem 7.2 actually holds for all Pokémon role-playing games, because the only actual Pokémon used in the construction were from the first generation, which is

present in all the games, and Enemy Trainers are of course present in all the games as well.

Acknowledgments

This work was initiated at the 25th Bellairs Winter Workshop on Computational Geometry, co-organized by Erik Demaine and Godfried Toussaint, held on February 6–12, 2010, in Holetown, Barbados. We thank the other participants of that workshop—Brad Ballinger, Nadia Benbernou, Prosenjit Bose, David Charlton, Sébastien Collette, Mirela Damian, Martin Demaine, Karim Douïeb, Vida Dujmović, Robin Flatland, Ferran Hurtado, John Iacono, Krishnam Raju Jampani, Stefan Langerman, Anna Lubiw, Pat Morin, Vera Sacristán, Diane Souvaine, and Ryuhei Uehara—for providing a stimulating research environment. In particular, Nadia Benbernou was involved in initial discussions of Super Mario Bros.

We also thank The Spriters Resource [11], VideoGameSprites [12], NES Maps [13], and SNES Maps [14] for serving as indispensable tools for providing easy and comprehensive access to the sprites used in our figures. Finally, of course, we thank Nintendo and the associated developers for bringing these timeless classics to the world.
